

# **Data Science Unit 1**

# **Introduction to Python**

# Python

**Guido van Rossum invented Python** in December 1989 while looking for a "'hobby' programming project that would keep him occupied during the week around Christmas" as his office was closed for holidays.

# Python Libraries

**Data Science Unit 1**

# **Data Types and Operators**

# Data Types

Data Type	Definition	Example
Integer	Whole numbers given from negative infinity to infinity	5, 3, -1, 1000
Float	'Floating point number' - has a decimal point in it	3.3, -2.4, 5.0
String	A set of letters, numbers or characters in general- surrounded by quotation marks	'Data is Awesome'
Tuple	Ordered sequence with fixed number of elements- surrounded by parenthesis	(1,2), ('Red', 'Green', 'Blue')
List	Ordered sequence with no fixed number of elements- surrounded by square brackets	[1,2], ['Red', 'Green', 'Blue']
Dictionary	Unordered collection of key value pairs. To access the value you need to use its key	{'Blue':5, 'Red' :2, 'Green':0}

# Collections

## List

## Tuple

## Dictionary

# Collections-Differences

Data Type	Ordered	Mutable	Unique Values	Denoted
<b>Lists</b>	Y	Y	N	[...]
<b>Dictionaries</b>	N	Y	N	{...}
<b>Tuples</b>	Y	N	Y	(...)
<b>Sets</b>	N	Y	Y	{...}

# Variables

## Restrictions

- Variable names cannot be just a number (i.e., 2, 0.01, 10000).
- Variables cannot be assigned the same name as a default or imported function (i.e., 'type', 'print', 'for').
- Variable names cannot contain spaces.

## Best Practices

- Variable names should be lowercase.
- A variable's name should be representative of the value(s) it has been assigned.
- If you must use multiple words in your variable name, use an underscore to separate them.

# Operators

Operator	What it does	Example
+	Adds	$1 + 1 = 2$
-	Subtracts	$3 - 2 = 1$
*	Multiplies	$4 * 4 = 16$
/	Divides	$5/2 = 2.5$
//	Quotient (after division rounds down to whole number)	$5//2 = 2$
**	Exponent	$3 ** 2 = 9$
=	Assigns value	$x = 2$
%	Modulo (finds remainder)	$5 \% 2 = 1$

# Booleans

**x = 2**

Boolean	Outcome
x is 2	True
x is 4	False
x is 2 and x is 4	False
x is not 2	False
x is 2 or x is 4	True

# Comparisons

Operator	What it does
==	Equals to
!=	Not equals to
>	Greater than
>=	Greater than or equals to
<	Less than
<=	Less than or equals to

# Changing Types

```
float(1)
```

```
1.0
```

```
int(2.0)
```

```
2
```

```
str(2.0)
```

```
'2.0'
```

# **Data Science Unit 1**

# **Strings and Indexing**

# String

**‘Hello World’**

0 1 2 3 4 5 6 7 8 9 10

# **Data Science Unit 1**

# **Collections**

**['Data', 1, 'London', 2.0]**

# Tuples

**(1,2,3)**

# Dictionary

**{'A':2, 'B':5, 'C':10}**

# **Data Science Unit 1**

# **Importing Libraries**

# Import

```
import math  
  
x = math.cos(2 * math.pi)  
print(x)
```

1.0

```
from math import pi  
  
x=pi  
print(x)
```

3.141592653589793

# **Data Science Unit 1**

# **Practice**

# **Data Science Unit 1**

## **Control Flow**

# Control Flow

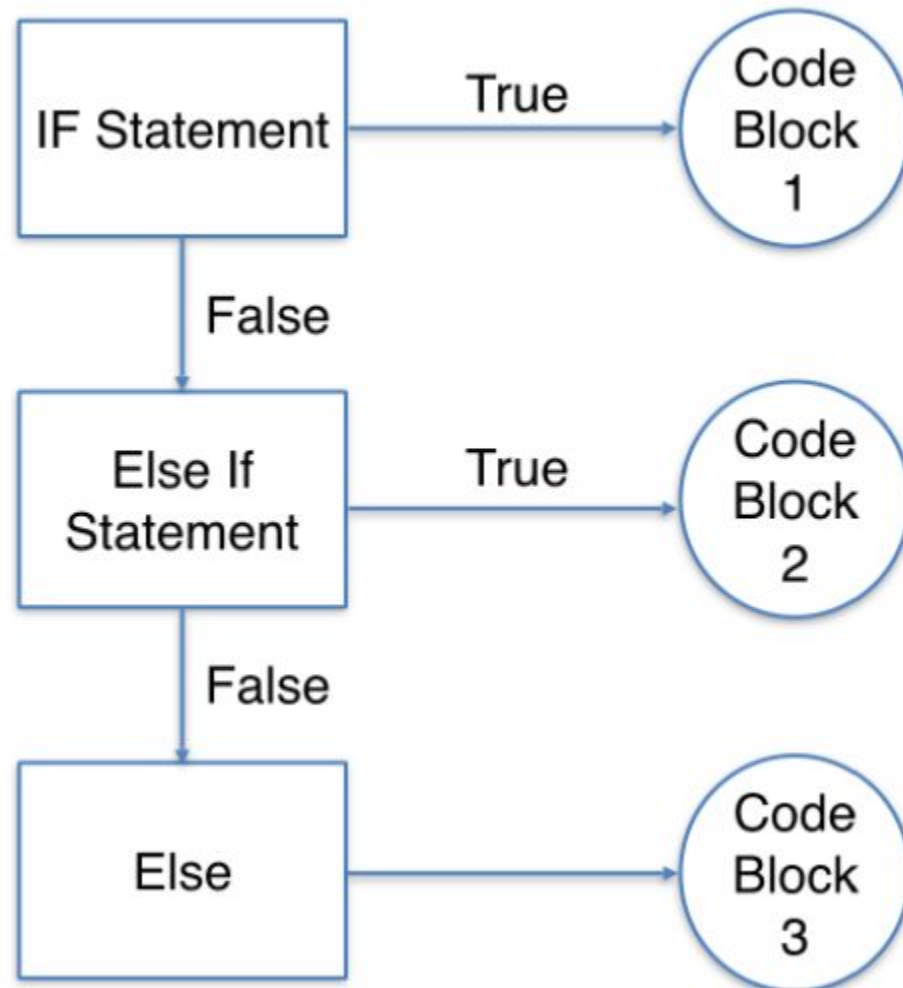

# Indentation

```
if 'one' == 'two':  
    print("The string 'one' is equal to the string 'two'.")  
  
print('---')  
print('These two lines are not indented, so they are always run next.')
```

# If/else

Executes First  
True Statement

Else is catch all and  
must be at the end

# For

```
numbers=[1,2,3,4,5]  
  
for number in numbers:  
    print(number**2)
```

```
1  
4  
9  
16  
25
```

# try-except

```
a = [1, 2, 3, 0]
for num in a:
    try:
        print(1 / num)
        #print('not executed due to the exception')
    except:
        print('Divide by zero!')

print('Program keeps executing!')
```

```
1.0
0.5
0.3333333333333333
Divide by zero!
Program keeps executing!
```

# Functions

```
def arithmetic(num1, num2):  
    """  
    This function adds, subtracts  
    and multiplies num1 and num2.  
    """  
    print(num1 + num2)  
    print(num1 - num2)  
    print(num1 * num2)  
  
#arithmetic(3,5)
```

# While

```
In [*]: x = 0
        while x < 10:
            print (x)
```

[illegible]

# List and Dictionary Comprehensions

```
# Create a new List which is an upper case version of the first list  
animals=['cat','dog','cow','mouse']  
upper_animals=[]  
  
for animal in animals:  
    upper_animals.append(animal.upper())  
  
print(upper_animals)  
  
['CAT', 'DOG', 'COW', 'MOUSE']
```

```
upper_animals=[animal.upper() for animal in animals]  
print(upper_animals)  
  
['CAT', 'DOG', 'COW', 'MOUSE']
```
